Topic Modeling, Sentiment and Election Markets

Applied LSA and sentiment analysis around the 2026 US midterms

FRE-GY 7871 · Assignment 5 · sample 2026-03-02 to 2026-10-09 (155 NYSE sessions) · 5,816 filtered tweets · built 2026-10-10T13:22

Latest consensus P(Dem): House 90.3%, Senate 61.8%, Democratic sweep 61.0%.

Executive summary

Stage 1 (sentiment → election odds). 0 of 21 tests survive the Benjamini–Hochberg correction at 10% (smallest q = 0.56); 1 of 21 reject at an unadjusted 5% level, about what chance alone delivers. At a daily horizon, public issue sentiment on X does not measurably lead prediction-market prices.

Covariance SVD. No factor of the lagged sentiment–return cross-covariance beats its circular-shift permutation null (p = 0.73, 0.24, 0.54); the leading factor's out-of-sample correlation is -0.29 (t = -2.3), the opposite sign to its training fit, which is what over-fitting looks like.

News check (GDELT). 0 of 48 tests of per-issue news salience and news tone on ΔProb survive FDR at 10% (smallest q = 0.11). X discourse tracks the news agenda most closely for Housing Affordability (ρ = 0.53), Foreign Policy/Defense (ρ = 0.50), Healthcare (ρ = 0.49); the median level correlation across issues is 0.31.

Stage 2 (election odds → assets). 7 of 57 excess-return tests and 0 of 57 volatility tests survive FDR at 10%.

Robustness. 5 of 7 survivors pass every check (HAC errors; without the 5 largest ΔProb sessions; without the 5 Jun 2026 sell-off; same sign in both halves; null placebo): ΔP(Sweep) → XLF (Σγ = -0.22, p = 0.003, both halves); ΔP(Sweep) → XLK (Σγ = +0.29, p = 0.002, mainly the second half); ΔP(Sweep) → UNH (Σγ = -0.46, p = 0.002, both halves); ΔP(Sweep) → NVDA (Σγ = +0.38, p = 0.006, mainly the second half); ΔP(Senate) → META (Σγ = +0.53, p = 0.004, mainly the second half). A rise in P(Dem senate) is followed the next session by outperformance of META. A rise in P(Dem sweep) is followed the next session by underperformance of XLF, UNH and outperformance of XLK, NVDA. The other survivors rest on a few extreme sessions or one half of the sample.

Rigobon–Sack. Relevance test p-values (Var_H/Var_L of ΔProb): House 0.629, Senate 0.034, Sweep 0.006. Even where the variance shift is significant it is too small to pin β down: 0 of 57 estimates have a 95% CI excluding zero, so contemporaneous causal effects are not identified in this sample.

Granger tests are predictive restrictions on lagged information, not structural effects. With one election cycle, read the q-values and the robustness battery rather than single p-values.

Figure 5. Granger tests: FDR q-values (darker = smaller)

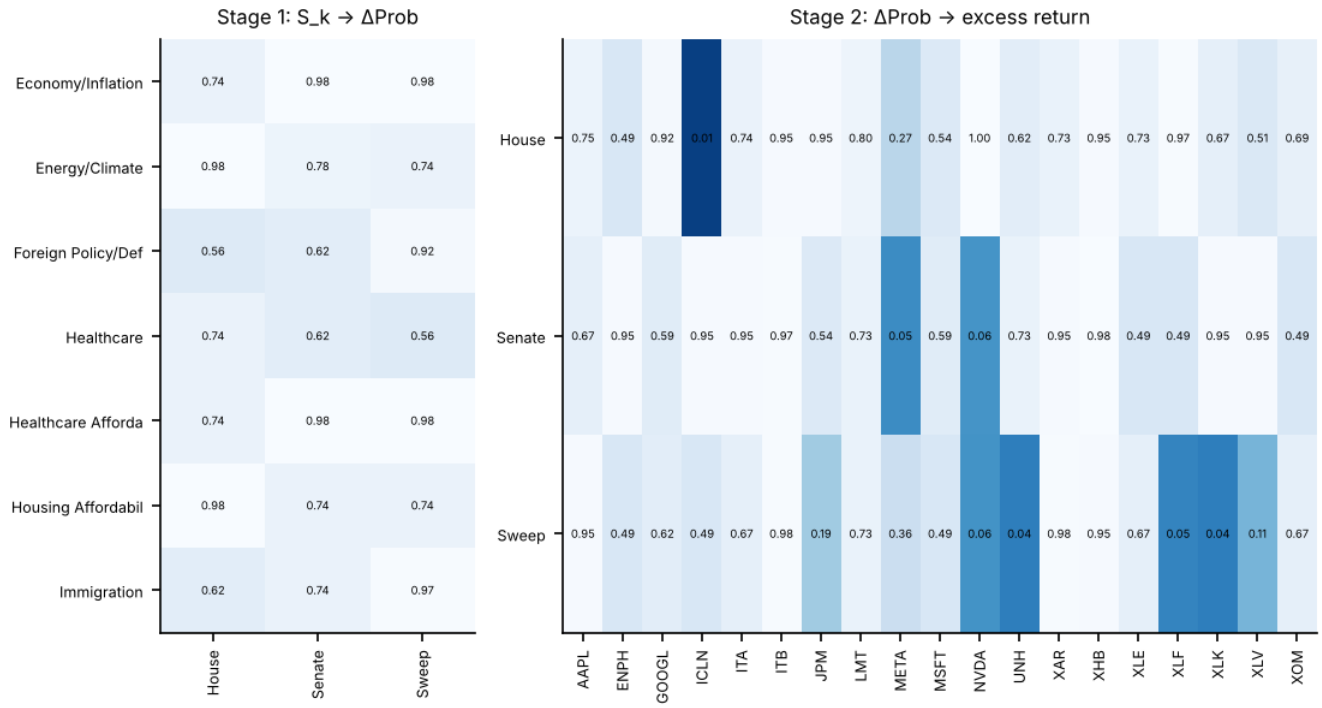

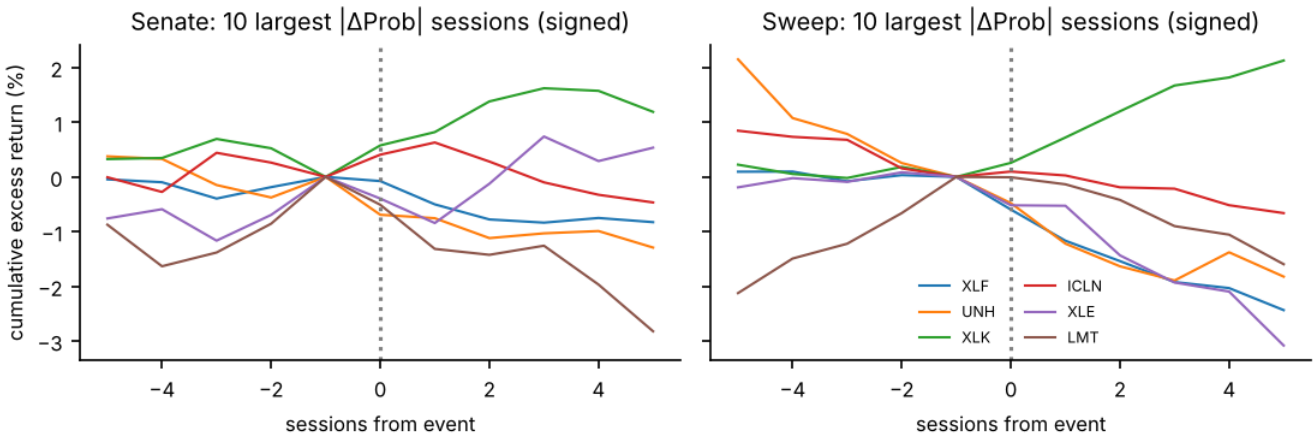

Figure 7. Basket reactions around large prediction-market moves

Methods

Calendar and timing. Everything lives on the NYSE calendar. Tweets are fetched per session (previous 16:00 ET close to this one), so weekend text lands on Monday. Prediction-market probabilities are the last hourly quote at or before 16:00 ET (median staleness: Kalshi 0 h, Polymarket 1 h). A GDELT day ends at 20:00 ET and counts for the next session. Returns never span a missing print.

Prediction markets. Kalshi (CONTROLH-2026, CONTROLS-2026, KXBALANCEPOWERCOMBO-27FEB) and Polymarket (control and balance-of-power markets), each normalised across all of its outcomes. Consensus = equal-weight average; PredictIt (daily bars only) is a cross-check with zero weight.

Text. twitterapi.io advanced search, two strata per session: a general issue × political-context query, and an affordability oversample (housing and healthcare costs) used for tone only. Server-side: English, no retweets or replies, 5–150 likes. Client-side: followers ≥ 10, views ≥ 100, astroturf (same text from ≥ 5 accounts). Budget: 93,450 credits, every call ledgered.

LSA. Uncentred TF-IDF (unigrams, bigrams, hashtags, cashtags; sublinear tf) → truncated SVD, k = 30 → varimax rotation of components 1..29. Centring would densify the matrix and treat unseen terms as negative evidence. Each pole is labelled by the share of its loading energy on an issue's seed terms (≥ 15%, purity ≥ 60%); stability = reappearance across 5 refits on 80% subsamples.

Sentiment. A document's weight on issue k is the squared cosine of its projection on k's poles. Polarity is VADER with an issue-specific overlay (e.g. 'rising' is negative for prices and rents). $S_{k,t} = \Sigma(\text{Pos} - \text{Neg})/\Sigma\text{Total}$ pooled over 5 sessions with ≥ 5 effective documents; gaps are filled only from the past.

Econometrics. ADF-tested series; Granger F-tests with HC1 errors, BIC lags and lagged SPY/ΔVIX/Δ2Y controls; Benjamini–Hochberg FDR per table; a robustness battery for every survivor. Covariance SVD of $(1/T)\Sigma\, s_{t-1}'\delta y_t$ on the first 60% of the sample, circular-shift permutation test, out-of-sample scoring on the remaining 40%. Rigobon–Sack $\beta = \Delta\text{Cov}/\Delta\text{Var}$ across H (top 20% GDELT midterm-news sessions) and L sessions, GDELT outage sessions excluded, regime bootstrap CI.

Topic-model comparison (baselines)

method	components	umass_coherence	topic_diversity	share_labelled	issues_found
NMF	12	-1.772	0.892	0.692	6
LDA	12	-1.724	0.658	0.686	5

Limitations

One campaign: 155 sessions. A daily Granger test has little power against effects that build over weeks.

The X sample is politically engaged mid-size accounts (median ~24–42k followers), not the median voter: posts that earn ≥ 5 likes mostly come from accounts with an audience.

Technology/AI never formed a topic, so the Big Tech basket is only tested against election odds.

GDELT's feed had 19 outage days (mid-September and most of October); those sessions are excluded from the regime split rather than read as quiet news days.

Yahoo daily closes for the S&P; 500 trackers disagree by 15–30bp a day over 25 Jun – 1 Jul 2026 (they agree on the week's total). Using the median of SPY/IVV/VOO as the benchmark, or dropping that week, changes no Stage 2 conclusion.

The robust Stage 2 results are lagged predictability. They fit slow pricing of regulatory risk, but with this many tests and one cycle they are hypotheses to test in 2028, not a trading rule.

AI use
